Abstract

We use representative data from household surveys in the euro area to describe differences in wages, income, consumption, wealth and liquid assets between households born in their country of residence (“natives”) and those born in other EU and non-EU countries (“immigrants”). The differences in wealth and liquid assets are more substantial than the differences in wages, income and consumption: immigrants earn on average about 30% lower wages than natives and hold roughly 60% less net wealth. For all variables, only a small fraction of differences between natives and immigrants—around 30%—can be explained by differences in demographics (age, gender, marital status, education, occupation, sector of employment). Immigrants are more likely to be liquidity constrained: while we classify 17% of natives as “hand-to-mouth” (they hold liquid assets worth less than two weeks of their income), the corresponding share is 20% for households born in another EU country and 29% for those born outside the EU. Employment rates of immigrants are substantially more sensitive to fluctuations in aggregate employment.

Keywords: migration, inequality, distribution of income and wealth

Annex 1: Oaxaca–Blinder decomposition

Seminal work of Oaxaca (1973) and Blinder (1973) decomposes differences between groups of households into an observed and an unobserved part. The method divides the group mean difference ($\mu_1 - \mu_2$) into two terms. The first one, commonly known as quantity effect, accounts for differences between the groups in observable characteristics (such as demographic variables). This term reflects that different compositions lead to unequal average outcomes. The second term captures the differences in coefficients, i.e., returns to observable characteristics. Given the same characteristics in individuals belonging to two distinct groups, the effects on the variable of interest are not the same. It is also known as coefficient effect, because it shows differences in returns for the two groups.

We apply the method considering two groups, natives and immigrants denoted by the index $i = \{N, I\}$, an outcome variable Y , logarithm of income, and a set of explanatory variables X containing demographic information like age, educational attainment and marital status. Let μ_i denote the unconditional sample mean of group i . We want to understand what drives the difference between the means $\mu_N - \mu_I$. A positive difference indicates that natives have higher income than immigrants. Denoting the unconditional mean for each group as: $\mu_i = E(Y_i) = \bar{X}_i \beta_i$, their difference can be written as:

$$E(Y_N) - E(Y_I) = (E(\bar{X}_N) - E(\bar{X}_I))' \beta_N + E(\bar{X}_I)' (\beta_N - \beta_I).$$

The first term on the right hand side, $(E(\bar{X}_N) - E(\bar{X}_I))' \beta_N$, captures disparities in the composition of the underlying population evaluated with the coefficients of the reference group, natives in our analysis. For example, if natives are older than immigrants, according to the life-cycle theory, their earnings should be higher. The second term, $E(\bar{X}_I)' (\beta_N - \beta_I)$ captures the differences in returns arising from the same set of characteristics. For example, if an additional year of experience has a higher impact on earnings of natives than immigrants, then $\beta_N > \beta_I$.

The size of the explained component is given by the first term; the rest of the gap is unexplained. The unexplained part reflects the effect of missing explanatory variables and other factors. In practice it is very hard to account for differences across households with observed characteristics only. This implies that the second, unexplained term is driven by factors, such as differences in preferences, beliefs, norms and cultural factors and discrimination or barriers.

Annex 2: Additional charts

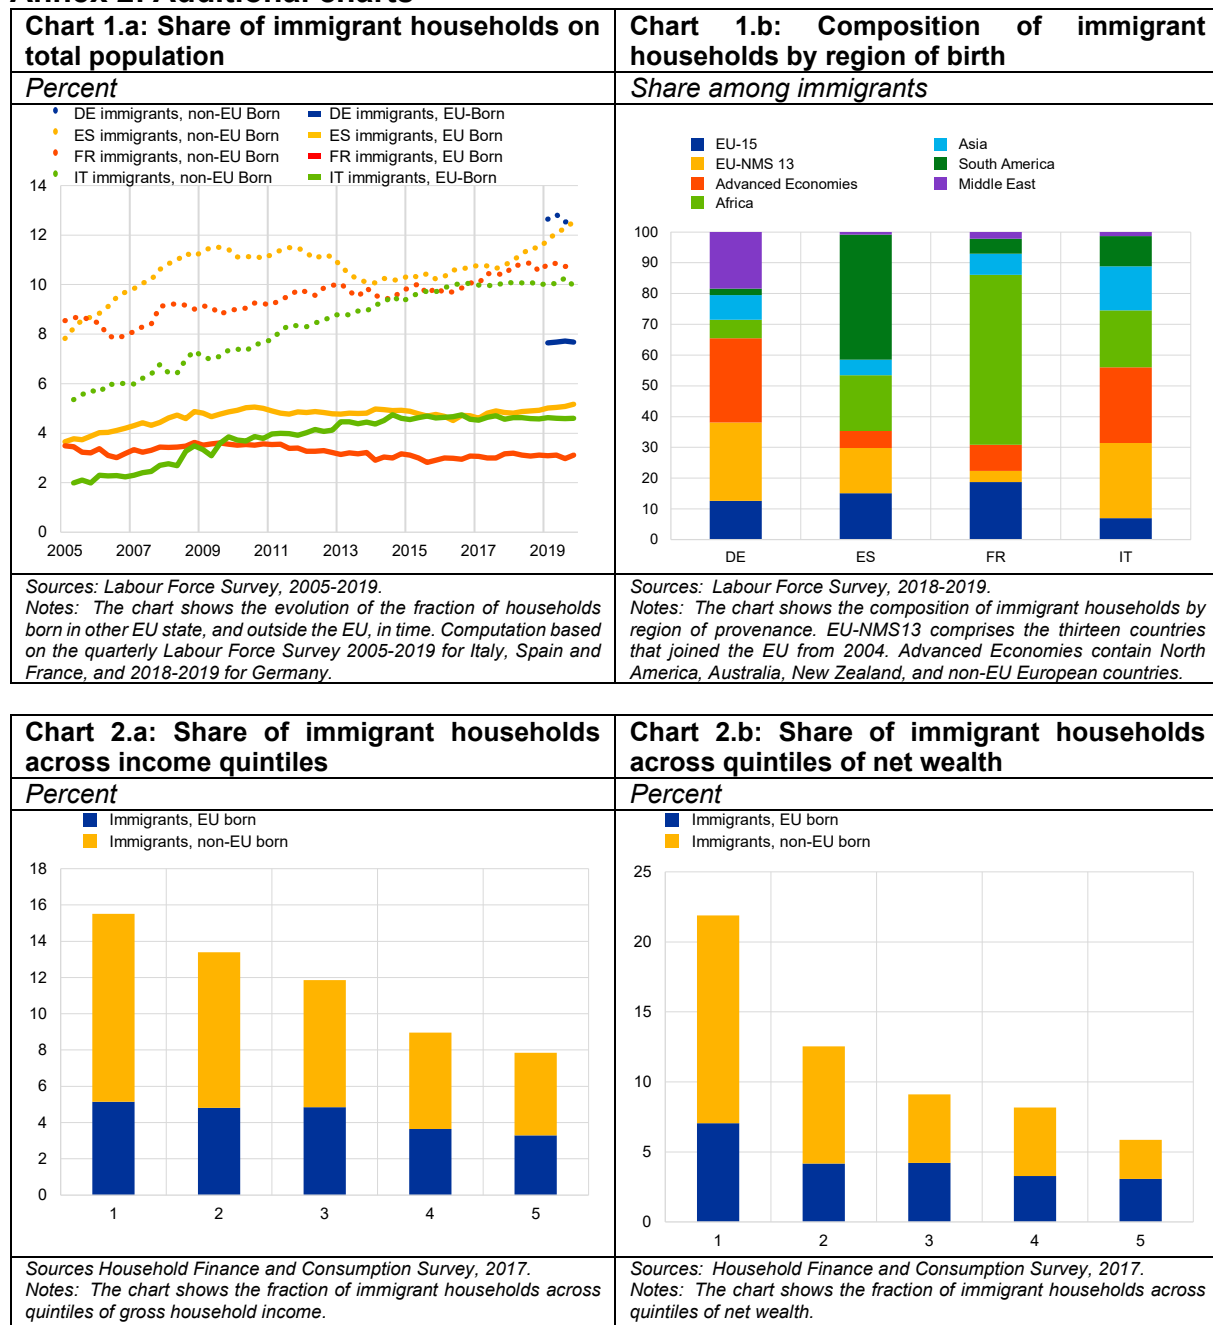

Chart 3: Age profiles of median gross hourly wages across countries

Sources: EU Statistics on Income and Living Conditions 2009-2018, Italy: 2009-2017.
 Notes: Hourly wages are calculated for employed individuals aged 18-64 (the self-employed are excluded). Due to data limitations the chart on hourly wages shows data for France, Italy and Spain. All reported numbers are medians.

Chart 4: Sensitivity of individual employment to aggregate employment by region of birth

Sources: Labour Force Survey 2005-2019, quarterly data.

Notes: The chart shows the sensitivity of individual employment, to aggregate the aggregate employment rate for various groups of households. EU-NMS 13 contains the thirteen countries that joined the EU from 2004. Advanced economies comprise North America, Australia, New Zealand, and non-EU European countries. The estimates average to 1 and are based on an aggregate of France, Germany, Italy and Spain. The lines indicate the 95% confidence interval.

Chart 5: Decompositions across the distribution, percentiles P25, P50 (median), P75

Chart 6: Oaxaca-Blinder decomposition for net wealth—Robustness to excluding employment status and sector of employment from explanatory variables

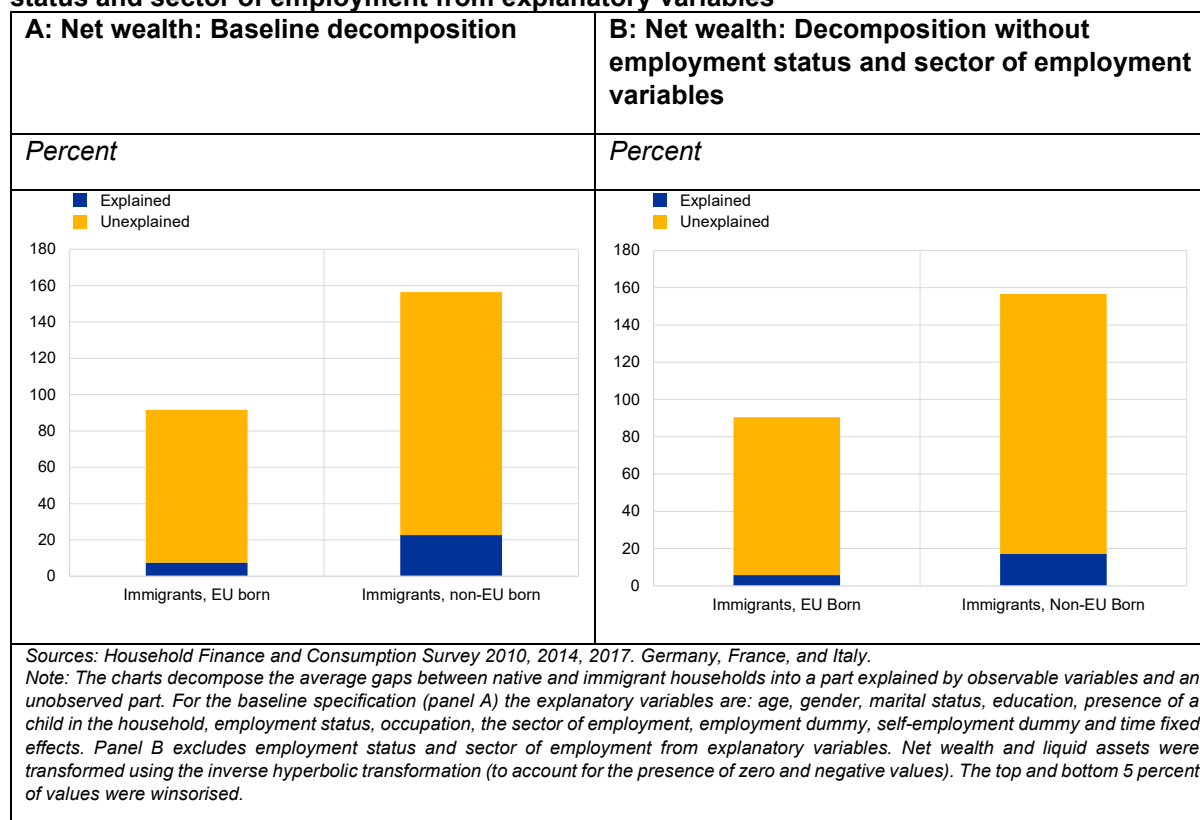

Chart 7: Oaxaca-Blinder decomposition for net wealth—Robustness restricting the sample to the employed only

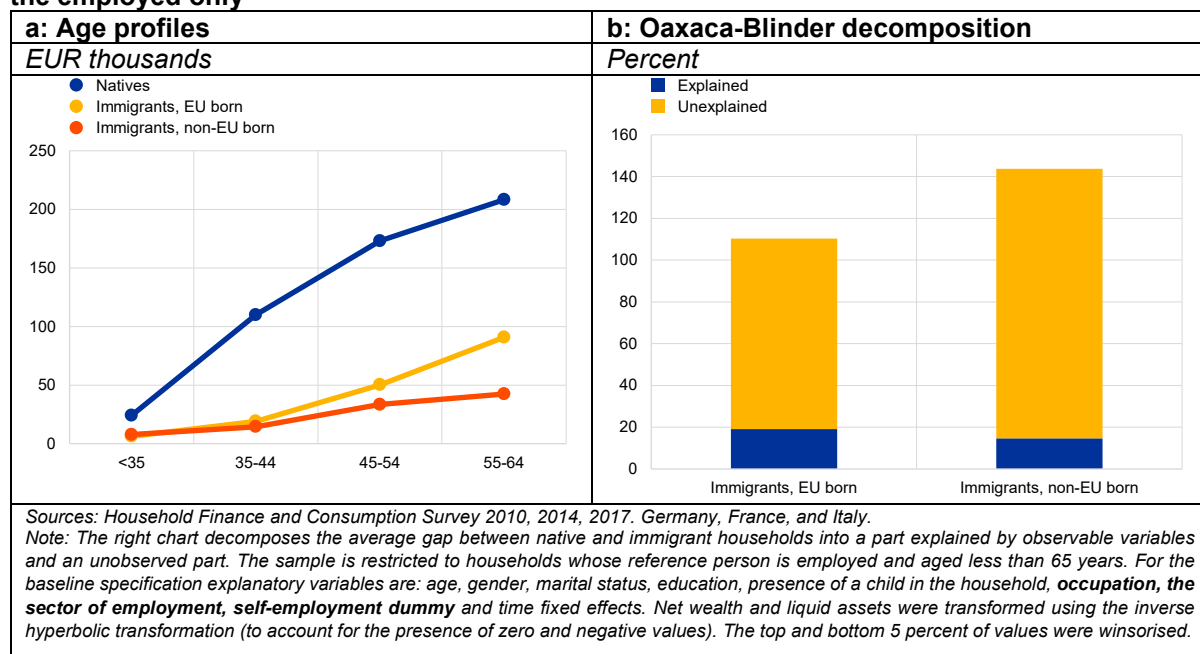

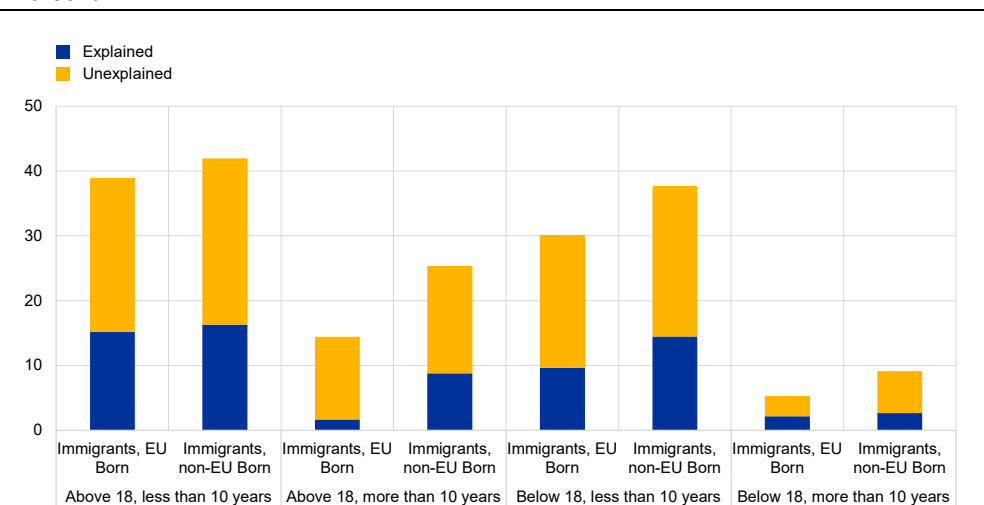

Chart 8: Oaxaca-Blinder decomposition for hourly wages—Breakdown by age of arrival and time spent in the current country of residence

Percent
